
HDR tone mapping using bilateral filtering

Reference material from
Durand and Dorsey
<http://people.csail.mit.edu/fredo/PUBLI/Siggraph2002/>

Theory

reduce contrast the low frequencies of the image while keeping the details (high frequencies).

Algorithm

$\text{intensity} = (20 \cdot R + 40 \cdot G + 1 \cdot B) / 61$

$[r, g, b] = [R, G, B] / \text{intensity}$

$\text{logIntensity} = \log_{10}(\text{intensity})$

$\text{logBase} = \text{Bilateral}(\text{logIntensity})$

$\text{logDetail} = \text{logIntensity} - \text{logBase}$

$\text{logOutputIntensity} = \text{compress}(\text{logBase}) + \text{logDetail}$

$\text{outRGB} = [r, g, b] * \text{pow}(10, \text{logOutputIntensity})$

Bilateral blur

- Blur, but not across edges.
 - Like a gaussian blur with an extra weight for the intensity.
 - Non linear -> not separable in theory, will lead to artifacts.
-

EFFECT SPOTLIGHT:
BILATERAL

BLUR

Base contrast compression

Suggested:

$\text{targetContrast} / (\max(\log\text{Base}) - \min(\log\text{Base}))$

$\text{targetContrast} = \log_{10}(5)$

Possible to use reinhard or other global tonemap operator to compress the contrast base.

Implementation

Input:

1 - 4: Tonemap function

1) Durand & Dorsey (bilateral)

2) Reinhard (global)

3) Filmic Games 'Uncharted 2' - Tonemap (global)

4) Durand & Dorsey with the compression used in 3, (bilateral)

S) Toggle Separable

Mouse scroll:

Control detail level, $\alpha = [0, 1]$

$\logOutputIntensity = \text{compress}(\logBase) + \alpha * \logDetail$
